

Javascript Single Page App

Overview

We will be using Javascript to create a single page app to show and display movie info.

Using the API from <http://www.omdbapi.com/>, construct a single page app that will have a search input box, movie search results, and movie detail portions.

This assignment is similar to we have introduced to students, and it reflects a real life scenario here in class.

Requirements

- Use either Angular or JQuery to solve this problem. If you would like, you can use some other front end javascript library (Backbone, Ember, React)
- Submit us a github link to the project with proper commit messages.

Bonus

- Though a backend is not required for this challenge, incorporating Rails for additional features of this app would impress us.
- Use a templating language of your choice for displaying results
- Use routing on your app, via # or pushstate features of javascript.
- Make it spiffy! Use Bootstrap or Foundation, or design your own html.

The OMDB Api is a nice API to use, however some of the images from the movie results are not hotlinkable outside of localhost. Don't worry about this for now.
